It is well known that low molecular weight alcohols, ethers, and other organic compounds are useful as fuel extenders or fuel additives to fuel blends. Ethanol is a preferred fuel additive to gasoline for use in automotive vehicles and marine applications because of its high octane number and its ability to serve as an oxygenate. This same oxygenate, in addition, has been shown to reduce engine deposits in the combustion chamber. While there are other oxygenates in the chemical industry that can be used as fuel additives, ethanol is more desirable because of its availability, its low cost, and its compatibility with current fuel systems. The oxygenates in other chemical industries are generally more expensive and consequently not as desirable for use in fuel. Ethanol is most advantageously added as an additive to gasoline in the form of a water-containing solution of ethanol and water. This type of ethanol-water solution is referred to as a "gasoline blend stock" and is often referred to as "gasohol." The production of "gasohol" is well documented in the patent literature as well as in the trade literature. One process, in particular, is disclosed in U.S. Pat. No. 3,093,625. There, ethanol is produced in a series of steps which include the fermentation of a readily available feed stock such as the starch-containing agricultural by-products, cane sugar, beet sugar, molasses, or wheat. The term "starch" is used generically to include the carbohydrates obtained from almost any source. The fermented feedstock is distilled to separate the ethanol from the other fermentation products. The fermented feedstock is then subjected to a cooking process to break down the hemicellulose and other materials and to increase the yield of fermentable sugars. The fermented feedstock may be separated into two fractions, one containing monosaccharides (including glucose, fructose, and galactose), and the other containing disaccharides and oligosaccharides. The monosaccharides fraction of the fermented feedstock is subjected to a catalytic hydrogenation to remove the oxygen, and to convert it to ethanol. The disaccharide fraction is subjected to an acid hydrolysis to convert the oligosaccharides to glucose. The glucose may be converted to a fermentable sugar by a saccharification process. Thereafter, the resulting syrup is distilled to separate the ethanol from the sugars. The sugar may be further separated into glucose and either dextrose (gluc

Field of the Invention The present invention relates to an image display device and an image display method. 2. Description of the Related Art There are several methods for displaying a stereoscopic image to a viewer. One of the methods is a passive method in which the viewer views a stereoscopic image, and other of the methods is an active method in which the viewer views a stereoscopic image by a special stereoscopic image display device. In general, the passive method is widely used. Thus, the viewer views the stereoscopic image displayed by a passive method and hence enjoys viewing a three-dimensional image. The viewer, however, is required to wear a special pair of eyeglasses or a special polarization eyeglasses to view the stereoscopic image displayed by the passive method. Thus, the passive method has various disadvantages. In particular, it is necessary to remember the special equipment and the special technique for viewing the stereoscopic image. Further, for viewing the stereoscopic image, the viewer is required to wear the special eyeglasses. Thus, the viewer may feel a fatigue to wear the special eyeglasses. On the other hand, the active method is relatively new. As the active method, there are various methods, such as a polarized eyeglasses method, a parallax barrier method, a lenticular lens method, a time division-multiplexing method, a shutter eyeglasses method, and the like. Thus, the active method has various merits. For example, in the active method
